PROJECT GUIDE : Dr. Kanmani K

ABSTRACT

Large Language Models (LLMs) such as ChatGPT, Claude, and Gemini are increasingly deployed in real-world applications including customer support, healthcare, education, and enterprise automation. However, these systems are vulnerable to prompt injection attacks, where malicious inputs manipulate the model into ignoring safety policies, leaking confidential data, or performing unauthorized actions.

This research proposes a hybrid detection framework that combines semantic analysis and behavioral analysis to identify malicious prompts before they influence model output. The system analyzes intent, instruction overrides, suspicious language patterns, and interaction behavior to classify prompts as safe or malicious.

By preventing adversaral manipulation at the input stage, the proposed framework enhances the security, reliability, and trustworthiness of LLM-based systems.

INTRODUCTION

- LLMs are widely used in AI assistants, enterprise tools, and automation systems
- These models follow natural language instructions without verifying intent
- Attackers exploit this behavior using prompt injection
- Malicious prompts can override safeguards and cause harmful actions
- Traditional cybersecurity tools cannot detect natural-language attacks
- There is a need for intelligent detection mechanisms

EXISTING SYSTEM AND ITS LIMITATIONS

Existing Systems

- Basic keyword filtering
- Rule-based moderation
- Output monitoring systems
- Manual prompt review
- Access control mechanisms

Limitations

- Easily bypassed through paraphrasing
- Cannot detect semantic manipulation
- No understanding of malicious intent
- Unable to detect indirect attacks
- Lack of behavioral analysis

MOTIVATION

- Rapid adoption of LLMs in sensitive domains
- Increasing cases of AI misuse and jailbreak attacks
- Risk of confidential data leakage
- Lack of reliable real-time defense mechanisms
- Need for secure AI deployment
- Importance of maintaining trust in AI systems

PROPOSED SYSTEM AND ITS ADVANTAGES

Proposed System:

A hybrid prompt injection detection framework integrating:

- Semantic intent analysis
- Behavioral pattern monitoring
- Risk scoring and classification
- Real-time input validation

Core Components

- Semantic Analysis Module
- Behavioral Analysis Module
- Decision Engine
- Alert & Blocking Mechanism

ADVANTAGES

- Detects malicious intent beyond keywords
- Resistant to paraphrased attacks
- Real-time prevention before model response
- Supports indirect attack detection
- Improves AI system security
- Enhances reliability of LLM applications

PROBLEM STATEMENT

Prompt injection attacks exploit the instruction-following nature of LLMs by embedding malicious commands within user inputs. These attacks can cause models to bypass safety rules, reveal confidential information, or generate harmful outputs.

Existing defenses rely primarily on rule-based filtering and post-response moderation, which are ineffective against sophisticated adversarial prompts. There is a critical need for a robust detection mechanism that can analyze both the semantic meaning of prompts and the behavioral patterns of user interactions to prevent manipulation of LLM systems.

OBJECTIVES

- The primary objective of this project is to investigate the vulnerabilities of large language models to prompt injection attacks and to develop an effective detection mechanism to mitigate such threats. The study aims to analyze the semantic characteristics of malicious prompts, including attempts to override instructions, extract sensitive information, or manipulate model behavior. Additionally, the project seeks to identify behavioral patterns associated with adversarial interactions, such as repeated attempts to bypass safeguards or gradual escalation of malicious intent. By combining semantic analysis and behavioral monitoring, the project proposes to design a hybrid detection framework capable of identifying and classifying prompts as safe, suspicious, or malicious in real time. Finally, the effectiveness of the system will be evaluated using standard performance metrics to ensure reliability and applicability in real-world LLM deployments.

LITERATURE SURVEY

S.No	Title (Name of the journal, author, and publication details)	Methodology	Identification of Gaps /Limitations
1	Perez, E., Ribeiro, I., 2022. *Prompt Injection Attacks Against Large Language Models.*	• Demonstrated direct prompt injection techniques • Evaluated LLM responses to adversarial instructions • Tested instruction override scenarios	• Focuses only on attack demonstration • No real-time detection mechanism • Lacks mitigation framework

S.No	Title (Name of the journal, author, and publication details)	Methodology	Identification of Gaps /Limitations
10	Carlini, N., et al., 2021. *Extracting Training Data from Large Language Models.*	• Demonstrated data extraction via adversarial queries • Analyzed privacy risks in LLM outputs • Evaluated vulnerability to malicious prompts	• Not focused specifically on prompt injection • No preventive mechanisms • Highlights need for stronger defenses

INFERENCE FROM LITERATURE SURVEY

- The literature survey reveals that prompt injection attacks represent a significant and emerging security threat to large language model applications. Existing research primarily focuses on demonstrating attack techniques or proposing isolated defense strategies, such as rule-based filtering or post-response moderation, which are often inadequate against sophisticated adversarial prompts. Many approaches lack the ability to understand the semantic intent behind user inputs and fail to consider behavioral patterns across interactions, making them vulnerable to paraphrased or indirect attacks. Furthermore, there is a noticeable absence of comprehensive real-time detection frameworks that integrate multiple defensive strategies into a unified system. These findings highlight the need for a robust hybrid approach that combines semantic analysis with behavioral monitoring to proactively detect and prevent prompt injection attempts before they compromise the integrity of LLM systems.

METHODOLOGY / TOOLS / ALGORITHM

Methodology

- Collect dataset of benign and malicious prompts
- Preprocess text data
- Extract semantic features
- Analyze behavioral patterns
- Train classification model
- Evaluate performance

Tools

- Python
- NLP libraries (Transformers, NLTK)
- Machine Learning frameworks
- Dataset repositories

ALGORITHM

- Step 1: User submits prompt P
- Step 2: Semantic analysis of P
- Step 3: Behavioral pattern evaluation
- Step 4: Feature extraction
- Step 5: Risk score computation
- Step 6: Classification (Safe / Suspicious / Malicious)
- Step 7: Allow or block prompt

SOFTWARE AND HARDWARE REQUIREMENTS

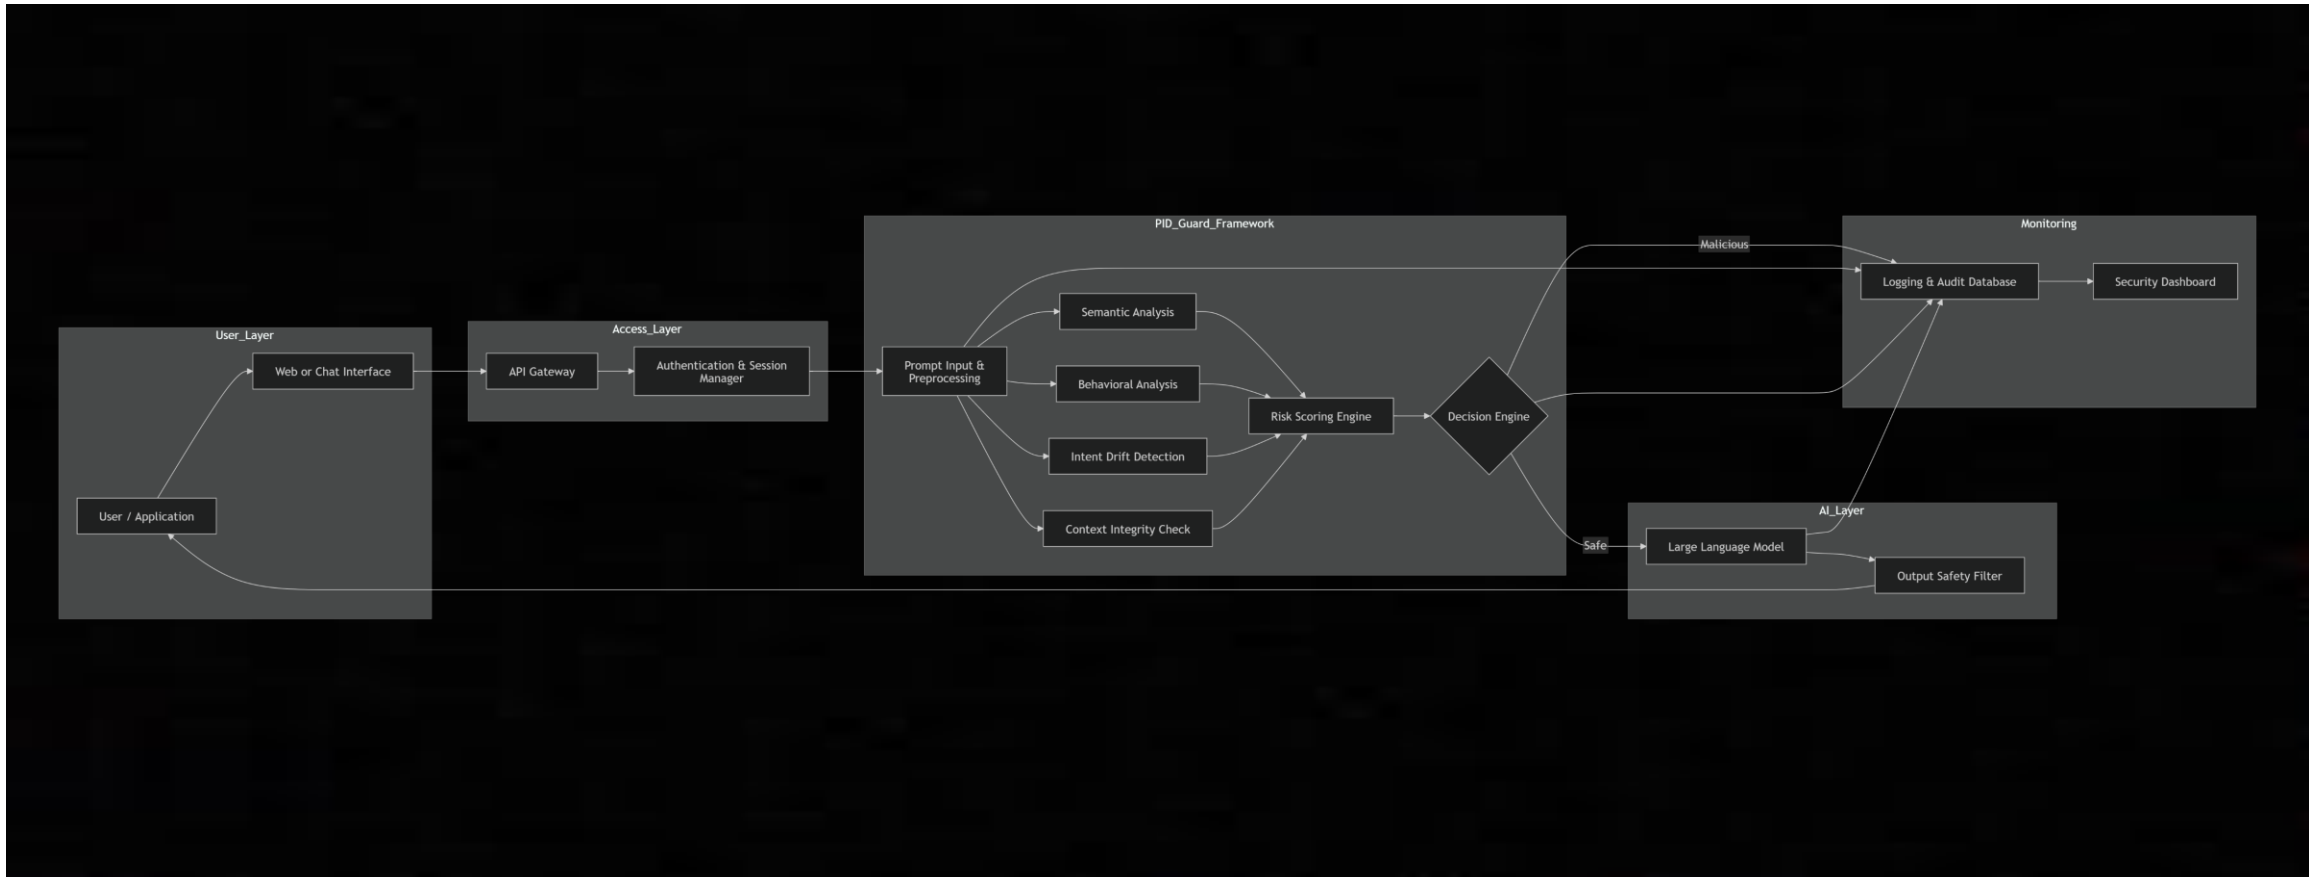
Software:

- Python Environment
- NLP Libraries
- Machine Learning Frameworks
- Operating System (Windows/Linux)
- Development Tools

Hardware:

- Minimum 8 GB RAM
- Intel i5 or equivalent processor
- Stable internet connection

ARCHITECTURE DIAGRAM



User Interaction Layer – Users or external applications submit prompts through a web interface, chatbot, or API client. Secure Session Manager maintains conversation context while preventing unauthorized access.

Interface & Access Layer – API Gateway receives incoming requests and routes them securely to the system. Authentication and rate-limiting mechanisms validate users, prevent abuse, and ensure controlled system access.

PID-Guard Framework Layer – Incoming prompts are analyzed using semantic analysis, behavioral analysis, intent drift detection, and context integrity monitoring to identify malicious or manipulative inputs. A risk scoring engine evaluates threat levels, and the decision engine determines whether to allow, sanitize, or block the request.

- **AI Model & Execution Layer** – Safe prompts are forwarded to the Large Language Model for processing, optionally interacting with external tools or knowledge bases. The model generates responses based only on validated inputs.

- **Monitoring Layer** – Generated responses are examined for policy violations, harmful content, or sensitive data leakage before being delivered to the user, ensuring safe and compliant outputs.

NOVELTY

- Hybrid semantic + behavioral detection approach
- Real-time input validation
- Detection of indirect attacks
- Focus on prevention rather than mitigation
- Applicable to multiple LLM platforms

MODULES

1. User Interface & Prompt Input Module
Provides a secure interface for users to submit prompts. Validates and preprocesses input before analysis.

2. Semantic Analysis Module
Examines the meaning of the prompt to detect malicious intent, instruction overrides, or sensitive requests.

3. Behavioral Analysis Module
Analyzes user interaction patterns such as repeated bypass attempts or suspicious query sequences.

4. Intent Drift Detection Module
Identifies gradual shifts from benign queries toward harmful objectives across multiple prompts.

5. Context Integrity Module
Ensures prompts do not override system rules or manipulate the model's internal instructions.

6. Feature Extraction & Scoring Module
Combines outputs from all analyses to compute a risk score for the prompt.

JUSTIFICATION OF SUSTAINABLE DEVELOPMENT GOAL

SDG 16 – Peace, Justice and Strong Institutions

- This research supports SDG 16 by enhancing the security, reliability, and accountability of AI-driven systems used in governance, business, and public services. By detecting prompt injection attacks that can manipulate AI outputs, leak sensitive information, or spread harmful content, the framework helps prevent misuse of artificial intelligence technologies.
- The proposed PID-Guard system strengthens trust in digital infrastructure by ensuring that AI applications operate safely and transparently even in adversarial environments. By protecting users and institutions from malicious manipulation of language models, the project contributes to resilient technological systems, ethical AI deployment, and secure decision-making processes aligned with responsible governance goals.

CONCLUSION

This research proposes a hybrid framework for detecting prompt injection attacks in large language models using semantic and behavioral analysis. By identifying malicious intent before model execution, the system enhances AI security, prevents misuse, and supports trustworthy deployment of LLM-based applications in real-world environments.
